High energy ν come from hadrons exiting horn 1 on-axis

Whats a beam "plug"?

In 2001, Brett Viren (following up on studies at IHEP) found that a 1.5cm radius graphite target placed between the 2 horns reduced the high energy tails in NuMI LE beam by $> 30\%$.

Summary and
Conclusions

$\bar{\nu}$ contamination in the ν beam < 3 GeV increases by 10%

$\nu_e + \bar{\nu}_e$ contamination in the ν beam < 5 GeV increases by 6%

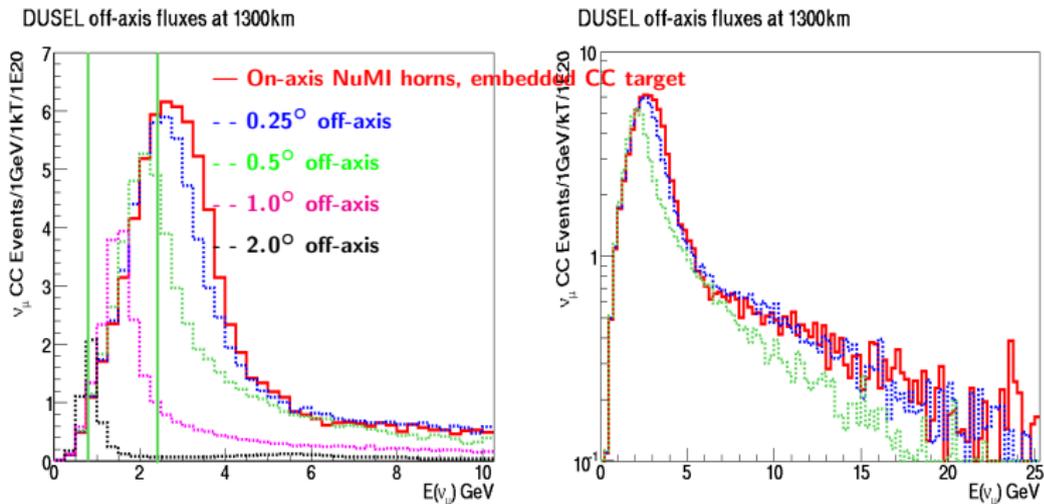

Pros:

- Most effective tool that reduces the HE flux exactly where you need it > 5 GeV without any impact at low energy.
- Might give you more ν at very low energies < 0.5 GeV - good for solar oscillations.
- Tunable - different plugs can be used.

Cons:

- Requires expensive material R&D and engineering
- Complicates operating - need to change out plugs.
- Complicates beamline geometry for Near-Far extrapolation

Another alternative to cutting down the high energy tails is going off-axis - redo calculation with optimized on-axis beam:

On axis flux is best for broad-band coverage

Beam Plugs

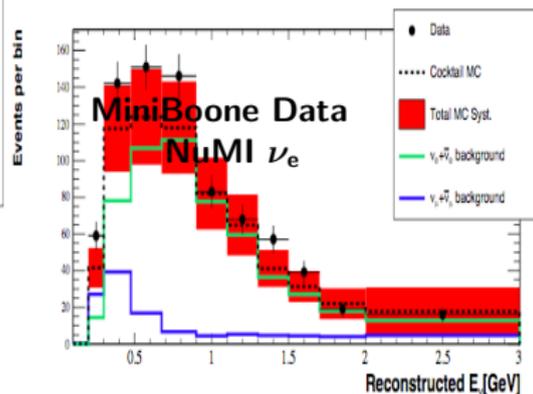

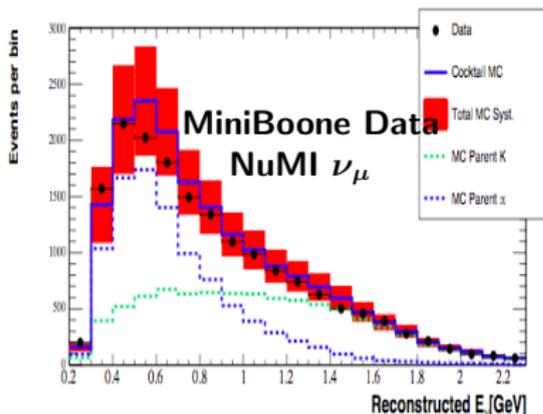

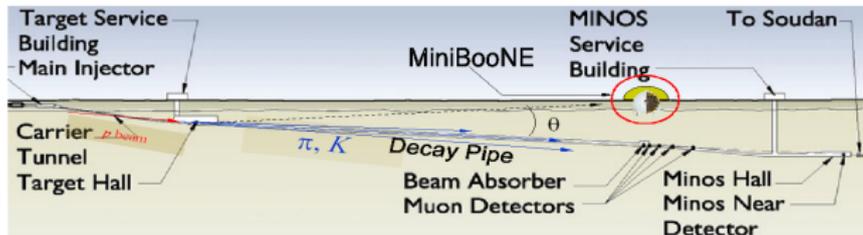

Going off-axis?

Helium Decay
Pipe

Beam Energy
Impact

Summary and
Conclusions

Pros:

- Effective at reducing HE tails.
- At high angles $> 1^\circ$ enhances flux at the 2nd oscillation maxima.
- NuMI/MiniBoone data confirms simulation predictions off-axis

Cons:

- **Throwing away beam flux at 1st osc maximum**
- **Limited tunability - WE CANT MOVE THE BEAMLINER!**
- Limited broad-band spectrum.

- **The decay pipe is the single most expensive element in the beamline. An evacuated DUSEL decay pipe would increase costs considerably.**
- **To reduce costs, the design will be for a He filled decay pipe at ~ 1 atm.**
- **He in the decay pipe acts as an absorber - esp for lower energy hadrons, in addition you can get extra HE ν from proton beam remnant interactions with He.**

We need to assess the impact of He in the DUSEL decay pipe

Summary and
Conclusions

NuMI/MINOS ran Jan 25, 2005- August 2007 with an evacuated decay pipe (0.4 Torr). In September 2007, filled with He at 682.6 Torr (0.9atm).

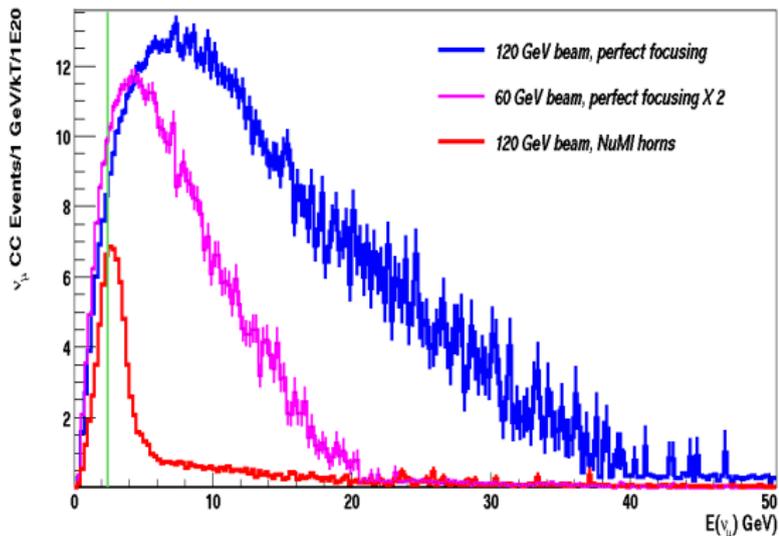

MINOS data: 2-3% increase in HE tails with He

DUSEL: This effect is dependant on decay pipe geometry

Study HE tails due to primary proton beam power using “PERFECT” focusing (no horns, set all hadron $p_T = 0$).

Effect of proton beam energy with perfect focusing

Lowering the beam energy is very effective at reducing HE tails

Summary and Conclusions

HE tails contribute 50-60% of NC background for ν_e appearance

HE tail (> 5 GeV) adjustments to Fluka05 MC

Adjustment	Effect	Comment
MINOS beam fit (Data)	$\sim +20\%$	10% more flux at < 5 GeV
He in beampipe (Data)	+3%	different beampipe geometry
1.5 m graphite plug (MC)	-38%	LE unchanged
0.5° off-axis (MC)	-38%	Less coverage at 1st maxima
p-beam 120 \rightarrow 60 GeV	-46%**	At the same power!

** Estimated using AGS focusing not NuMI

With 120 GeV protons, plug is the best option for lowering HE tails

Beam Energy
Impact

Summary and
Conclusions

- **Waiting for results of MINOS efforts to model He in decay pipe using Fluka08 to finish He study.**
- **Continue study tunability of plugs - should we have a plug moves along the beam axis? Early studies indicate this changes where the cutoff in energy starts.**
- **Move horns even closer?**
- **Target material properties (Jim & Byron)**
- **After Byron and Jim agree on a beam pipe shape - put all effects in MC: MINOS ND data corrections, correct target material, He in beam pipe, best plug and/or off-axis angle, decay pipe optimized to reduce volume. RECALCULATE SENSITIVITIES.**
- **Suggestions, please?**
